What is OpenWrt

- Project history
- Context
- State of art

What is OpenWrt

- ▶ contraction of Opensource Wireless Technology
- ▶ minimalist GNU/Linux distribution GPL licensed
- ▶ set of Makefile providing the building of a full filesystem
- ▶ package and updates repository

Introduction

- The different versions
- Adding support for a new target
- Customizing the system
- Getting support
- Becoming a developer

What is OpenWrt

Project history

Context

State of art

Project history

- ▶ OpenWrt was created by Gerry Rozeman (aka Groz) and Mike Baker (aka [mbm]) in november 2003.
- ▶ Since the beginning, Gerry and Mike felt the great potential offered by a Linux-based firmware, and at the same time the limitations provided by the Linksys one. That is why they decide to replace the later by a minimalist one, built with the current uClibc buildroot.
- ▶ The philosophy is simple : everything is configured in commmand-line using SSH

Introduction

- The different versions
- Adding support for a new target
- Customizing the system
- Getting support
- Becoming a developer

What is OpenWrt

Project history

Context

State of art

Context

- ▶ At the time the first OpenWrt version is released, Sveasoft firmwares were already available since few months and add various features, configurable through the Linksys web interface.
- ▶ Few months later, DD-WRT firmware comes out, an OpenWrt fork, the main reason for its developpement is the lack of an OpenWrt web interface.

Introduction

The different versions
Adding support for a new target
Customizing the system
Getting support
Becoming a developer

What is OpenWrt
Project history
Context
State of art

State of art

Nowadays, OpenWrt team is composed of 5 main developers, helped by many contributors :

- ▶ Mike Baker ([mbm])
- ▶ Imre Kaloz (Kaloz)
- ▶ Nicolas Thill (Nico)
- ▶ Felix Fietkau (nbd)
- ▶ Florian Fainelli (florian)

Interests of OpenWrt

Subversion repository organisation

The subversion repository is divided into several directories :

- ▶ 2 branches : **whiterussian/** and **buildroot-ng/**
- ▶ 5 tags : whiterussian_rc1 to 5
- ▶ 1 packages directory : **packages/**
- ▶ kamikaze in trunk (currently being migrated to **buildroot-ng/** and **packages/**)

Whiterussian

Whiterussian is currently the stable version of the OpenWrt firmware. It runs fine on devices based on Broadcom 947xx and 953xx boards, such as :

- ▶ Linksys WRT54G v1.0 to v4
- ▶ Asus WL-500g (Deluxe, Premium)
- ▶ Motorola WR850G, WE500G
- ▶ Buffalo WBR-B11, WBR-G54, WLA-G54

It is being used a firmware basis by several Wireless User Groups, and some companies, such as FON(fonbasic firmware).

Kamikaze
Kamikaze limitations
buildroot-ng
Main tasks
Interests of OpenWrt

Whiterussian limitations

Although the firmware runs fine, it is currently being limited by :

- ▶ the usage of a binary Broadcom Wi-Fi driver, thus restricting to a 2.4 kernel
- ▶ the difficulty to maintain and port packages
- ▶ the hardware support limited to Broadcom 47xx/53xx boards
- ▶ a web interface too much relying on the existence of a NVRAM

Kamikaze I

As a consequence to these difficulties, and the more and more increasing market of Linux-based hardware, the **Kamikaze** branch was opened.

New hardware platforms were then supported :

- ▶ Texas Instruments AR7 (noyau 2.4)
- ▶ Atheros AR531x (noyau 2.4)
- ▶ Aruba (noyau 2.6)
- ▶ x86 (noyaux 2.4 et 2.6)

Kamikaze II

- ▶ Broadcom SiByte (noyau 2.6)
- ▶ AMD Alchemy (noyau 2.6)
- ▶ Intel Xscale IX42x (noyau 2.6)
- ▶ Router Board RB532 (noyau 2.6)

Kamikaze limitations

Kamikaze has a certain number of drawbacks :

- ▶ difficulty in stabilising the kernels, most of the hardware platforms are not fully fonctionnal (Wi-Fi is not working most of the time)
- ▶ adding and maintaining packages is too close to the whiterussian way
- ▶ maintaining 2 distinct repository using different toolchains

Interests of OpenWrt

buildroot-ng

- ▶ abstraction et simplification d'écriture des fichiers **Makefile** et compatibilité avec la syntaxe précédente
- ▶ les paquetages dépendant fortement du noyau vont dans **buildroot-ng**, les autres dans **packages/**
- ▶ dépôt multi-architectures indépendamment du système de base

Conventions
target/Config.in
target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

Legal concerns

Some legal concerns are raised when you know a hardware is running Linux : Plusieurs questions légales se posent lorsque vous avez connaissance qu'un matériel donné fonctionne sous Linux :

- ▶ does the manufacturer provide the firmware source code ?
- ▶ does this hardware use binary drivers ?
- ▶ are we sure it is Linux or uClinux ?
- ▶ is the GPL code compliant with GPL or compatible ?

Introduction
The different versions

target/Config.in
target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

Proving that a hardware is running Linux

You have different ways of proving that a hardware is running Linux :

- ▶ downloading a firmware and trying to split it in : bootloader, kernel, filesystem (beware of the Big/Little Endian traps!)
- ▶ plugging a serial console and/or JTAG
- ▶ using a bug in the web interface to get the result of a dmes, `cat /proc/xxxx`

Introduction

target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

GPL violation

In conformance to the GPL, using GPL codes for commercial products implies the following things :

- ▶ publishing kernel sources
- ▶ publishing source code of the GPL applications used in the filesystem
- ▶ publishing sources of the GNU toolchain and the filesystem creation tools

In cas of a GPL violation, please inform :

<http://gpl-violations.org>

Introduction
The different versions

Conventions
target/Config.in
target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

Working basis

Your working basis is composed of the following elements :

- ▶ Linux kernel sources, modified to support the hardware, with the latest patches for your architecture (arm, mipsm ppc ...)
- ▶ binary drivers and firmwares for the Wi-Fi card, Ethernet, ADSL ...
- ▶ binary tools to create the firmware : CRC calculation, version, padding ...

You are very likely not to be able to get a fonctionnal firmware with the manufacturer tools.

Introduction
The different versions
Adding support for a new target
Customizing the system
Getting support
Becoming a developer

Legal concerns
Proving that a hardware is running Linux
What if the manufacturer does not provide sources
Working basis
Evaluation of the porting effort
Adding a new architecture to buildroot-ng
Conventions
target/Config.in
target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

Evaluation of the porting effort

According to what we have, to get a working port for the architecture with OpenWrt and being GPL compliant, we have to :

- ▶ analyse and generate differences between a vanilla kernel and the given one
- ▶ create a program adding the correct header in the firmware file (CRC calculation, version, padding ...)
- ▶ keep compatibility with the binary drivers and the current kernel version (beware of the VERSIONING option)
- ▶ eventually reverse engineer the binary drivers

- Introduction
- The different versions
- Adding support for a new target**
- Customizing the system
- Getting support
- Becoming a developer

- Legal concerns
- Proving that a hardware is running Linux
- What if the manufacturer does not provide sources
- Working basis

- Adding a new architecture to buildroot-ng**
- Conventions
- target/Config.in
- target/linux/architecture-2.x/Makefile
- target/image/architecture/Makefile
- include/target.mk
- Debuging and stabilising the port
- Further problems

Adding a new architecture to buildroot-ng

Now that we have the requirements for having an OpenWrt system for our architecture, let's add it :

- ▶ add an entry in **target/Config.in**
- ▶ add a directory **target/linux/architecture-2.x** (2.4 or 2.6 kernel) containing the arch-specific patches and kernel configuration
- ▶ add a directory **target/image/architecture** describing how to build the firmware image
- ▶ calling the kernel template in **include/target.mk**

Introduction
The different versions
Adding support for a new target
Customizing the system
Getting support
Becoming a developer

Legal concerns
Proving that a hardware is running Linux
What if the manufacturer does not provide sources

Further problems

Debugging and stabilizing

Common debugging tools :

- ▶ GDB
- ▶ EJTAG (si disponible)
- ▶ ksymoops
- ▶ usage of printk
- ▶ debug options enabled in the kernel
- ▶ bootloader documentation (RedBoot, CFE, YAMON, RomE ...)
- ▶ asking for help of users and developers

Adding a new architecture to buildroot-ng
Conventions
target/Config.in
target/linux/architecture-2.x/Makefile
target/image/architecture/Makefile
include/target.mk
Debuging and stabilising the port
Further problems

Further problems

Once you get a kernel booting on your hardware, it is very likely not to be directly usable, you may encounter the following issues :

- ▶ drivers working not correctly or not at all
- ▶ unrecognized flash mapping
- ▶ low reaction system (processor caching)

Customizing the system

You can highly customize your system, such as :

- ▶ adding a captive portal, RADIUS server
- ▶ doing advanced filtering using iptables
- ▶ adding network stacks and protocols ...
- ▶ adding drivers for various hardware : webcam, additional Wi-Fi stick ...
- ▶ adding features to **webif**

Adding packages

We invite you to participate to the migrating effort of the packages in **kamikaze** and make them use the **buildroot-ng** syntax.

In opposition to the previous system, where you had to create 3 files :

- ▶ Makefile
- ▶ Config.in
- ▶ ipkg/paquetage.control

buildroot-ng describes and abdstracts everything in a **Makefile**.
